Applicant(s)

BORCK ET AL.

Examiner

GREGORY CLARK

Art Unit

1794

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --
Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

- 1) ☐ Responsive to communication(s) filed on ____.
- 2a) ☒ This action is **FINAL**. 2b) ☐ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

- 4) ☒ Claim(s) 1,3-7,9-21,24 and 25 is/are pending in the application.
- 4a) Of the above claim(s) ____ is/are withdrawn from consideration.
- 5) ☐ Claim(s) ____ is/are allowed.
- 6) ☒ Claim(s) 1,3-7,9-21,24 and 25 is/are rejected.
- 7) ☐ Claim(s) ____ is/are objected to.
- 8) ☐ Claim(s) ____ are subject to restriction and/or election requirement.

Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☐ The drawing(s) filed on ____ is/are: a) ☐ accepted or b) ☐ objected to by the Examiner.
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some * c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
 2. ☐ Certified copies of the priority documents have been received in Application No. ____.
 3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

Attachment(s)

- 1) ☐ Notice of References Cited (PTO-892)
- 2) ☐ Notice of Draftsperson's Patent Drawing Review (PTO-948)
- 3) ☐ Information Disclosure Statement(s) (PTO-8508)
Paper No(s)/Mail Date ____
- 4) ☐ Interview Summary (PTO-413)
Paper No(s)/Mail Date ____
- 5) ☐ Notice of Informal Patent Application
- 6) ☐ Other: ____

DETAILED ACTION

Claim Rejections - 35 USC § 103

1. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

2. **Claims 1,3-7, 9-20 and 24-25 are rejected under 35 U.S.C. 103(a) as being unpatentable over Elliot (2003/0236567) in view Collombel (5,166,187) and Pastorello (6,642, 213).**

3. **Regarding Claims 1**, Elliot teaches an implantable prosthesis which may be used as a graft to replace a portion of a bodily passageway (e.g., vascular graft), or may be used within a bodily passageway such as an endovascular stent-graft (paragraph 20). The implantable stent formed can be made of a metal, such as stainless steel, tantalum, or niobium (paragraph 22). Elliot teaches that the skirt (outer covering the prosthesis) can be coated with materials that are susceptible to cell ingrowth (tissue simulating) (paragraph 25) and the one or more skirts (partial areas or partial layers) can be provided to form seal along various points about the prosthesis (paragraph 26). These materials include: collagen, fibrin, hyaluronic acid, chitosan, and/or other polysaccharide (paragraph 25). Elliot does not teach a coating

composition the *vivo* degradation of the polysaccharide layer is slowed from the outside in the direction of the main body of the implant or where a single layer is composed of hyaluronic acid and chitosan.

Collombel teaches that chitosan can be used to coat prostheses (column 14, lines 2-5) and the speed of the enzymatic degradation of chitosan is a function both of its molecular weight and its degree of acetylation (Column 5, lines 64-66).

Pastorello teaches that the chemical structure of the hyaluronic acid derivative used and according to the degree of esterification allow the degradation times to be adjusted according to the requirement of the area to be reconstructed (Column 3, lines 55-61).

Elliot teaches an implantable prosthesis which can be composed of hyaluronic acid and chitosan. Pastorello and Collombel teach that both hyaluronic acid and chitosan can be selected with the appropriate structural features (esterification in hyaluronic acid and acetylation in chitosan) to control the degree of degradation in a given region.

In addition, the simple esterification of hyaluronic acid and acetylation of chitosan is achieved by a well known condensation reaction procedures. Moreover, the blocking of reactive organic groups such as the carboxylic acid group or the hydroxyl group is a well known method to decrease the reactivity of an organic material to a given medium. To control the degradation rate a person skilled in the art would conduct routine experiments to ensure that a suitable percentage of reactive organic groups were blocked to control the degradation rate.

The examiner takes the position that Collombel and Pastorello teaches the very structural features (esterification in hyaluronic acid and acetylation in chitosan) and molecular weight requirements necessary for a person of ordinary skill in the art at the time of the invention to formulate prosthetic coatings with a controlled degradation rate in a given region.

The process would involve ensuring that through routine experimentation that the chitosan on the external portion of the coating structure has a sufficient molecular weight and a suitable level of acetylation to slow the polysaccharide degradation by a desired amount for the intended application. Likewise, ensuring that through routine experimentation that the hyaluronic acid on the external portion of the coating structure have a suitable level of esterification to slow the polysaccharide degradation by a desired amount for the intended application.

With a reasonable expectation of success, a person of ordinary skill in the art with the teachings of Elliot, Collombel and Pastorello would modify the chitosan and hyaluronic acid of Elliot with the acetylated chitosan of Collombel and the esterified hyaluronic acid of Pastorello in order control the rate of degradation.

The motivation for combining the references would have been to utilize known techniques to control the degradation rates of chitosan and hyaluronic acid on coated implants to improve compatibility with surrounding tissue and decrease the likelihood of infection.

The examiner takes the position that Elliot discloses that hyaluronic acid and chitosan can be used as biodegradable coating materials for implants. The simple

combining or two polysaccharide materials (to form a single layer) for which the cited reference teaches utility as implant coating materials is not considered as patentable subject matter.

4. **Regarding Claim 3**, Elliot teaches an implantable prosthesis that can be made from materials that include: collagen, fibrin, hyaluronic acid, chitosan, and/or other polysaccharide materials (paragraph 25).

As Elliot uses a like material (chitosan) in a like manner as claimed, it would be expected that the prosthesis (implant) would have the same characteristics claimed, particularly the adhesion properties, absence a showing of unexpected results.

5. **Regarding Claim 4**, Elliot teaches an implantable prosthesis that can be made from materials that include: collagen, fibrin, hyaluronic acid, chitosan, and/or other polysaccharide (paragraph 25). The applicant claims a thickness of 1 to 50 microns. Elliot does not teach the thickness of the chitosan layer.

With a reasonable expectation of successful results, it would have been obvious to one having ordinary skill in the art at the time of the invention to adjust the thickness for the chitosan layer to ensure that a sufficient amount of the adhesive layer was present to avoid slippage of the implanted prosthesis. Such routine experimental would have resulted in a thickness range that covers the ranges in the instant claim.

6. **Regarding 5**, Elliot teaches that the skirt (outer covering the prosthesis) can be coated with materials that include: collagen, fibrin, hyaluronic acid, chitosan, and/or other polysaccharide (paragraph 25). The applicant teaches a total weight of polysaccharide of not more than 50% weight. Elliot does not teach a weight percent for the polysaccharide layer.

With the reasonable expectation of success, it would have been obvious to one having ordinary skill in the art at the time of the invention to add a sufficient amount of polysaccharide material for adequate coverage of the prosthesis. Such routine experimentation to determine the appropriate amount would result in a polysaccharide level that overlaps with the applicant.

7. **Regarding Claims 6 and 7**, Elliot teaches an implantable prosthesis which may be used as a graft to replace a portion of a bodily passageway (e.g., vascular graft), or may be used within a bodily passageway to maintain patency thereof, such as an endovascular stent-graft (paragraph 20). These materials include: collagen, fibrin, hyaluronic acid, chitosan, and/or other polysaccharide (paragraph 25). Elliot does not teach an average molecular weight of the hyaluronic acid or hyaluronic acid derivative between 300,000 and 500,000 Dalton or between 380,000 and 420,000 Dalton at claimed by the applicant.

With the reasonable expectation of success, a person of ordinary skills in the art at the time of the invention through routine experimentation would adjust the molecular weight of hyaluronic acid or its derivatives based on the amount of

durability required for that component. Hyaluronic acid or its derivatives with higher molecular weights would be expected to be more durable than hyaluronic species with lower molecular weights. The determination of the appropriate average molecular weight would overlap with the ranges taught by the applicant in the course of optimization.

8. Regarding Claims 9 and 11, Elliot does not teach that the internal area of the polysaccharide layer is not degradable, at least completely within two years or the external polysaccharide layer is degradable within 100 days as claimed by the applicant.

Pastorello teaches that the chemical structure of the hyaluronic acid derivative used and according to the degree of esterification allow the degradation to be adjusted according to the requirement of the area to be reconstructed (Column 3, lines 55-61).

Collombel teaches the usage of chitosan in a biomaterial application where the speed of enzymatic degradation of chitosan is a function both of its molecular weight and its degree of acetylation (Column 5, lines 64-66).

Whereas, Elliot teaches an implantable prosthesis which can be composed of hyaluronic acid and chitosan. Pastorello and Collombel teach that both hyaluronic acid and chitosan can be selected with the appropriate structural features (esterification in hyaluronic acid and acetylation in chitosan) to control the degree of degradation.

It would have been obvious to a person of ordinary skill in the art at the time of the invention to combine the biocompatible hyaluronic acid and chitosan implantable prosthesis coating taught by Elliot with the suitable structural features (esterification in hyaluronic acid and acetylation in chitosan) taught by Pastorello and Collombel to give the desired degradation properties in the respective layers to improve tissue compatibility and the decrease the likelihood of infection.

9. **Regarding Claims 10 and 12**, Elliot, Pastorello, and Collombel do not teach an internal of polysaccharide layer thickness of 3 to 50 microns or an external thickness of 10 to 250 microns as claimed by the applicant. Elliot does not teach the thickness of the polysaccharide layer.

With a reasonable expectation of successful results, it would have been obvious to one having ordinary skill in the art at the time of the invention to adjust the internal and the external thicknesses for the polysaccharide layers through routine experimentation of implant coating levels to determine the appropriate amount which would include the ranges claimed by the applicant.

10. **Regarding Claims 13, 14, 16**, Elliot teaches that the skirt (outer covering the prosthesis) can be coated with materials that are susceptible to cell ingrowth (tissue simulating) (paragraph 25) and the one or more skirts (partial areas or partial layers) can be provided to form seal along various points about the prosthesis (paragraph 26). These materials include: collagen, fibrin, hyaluronic acid, chitosan, and/or other

polysaccharide (paragraph 25). Elliot, Pastorello, and Collombel do not teach a composition such the vivo degradation of the polysaccharide layer is slowed from the outside in the direction of the main body of the implant, an internal polysaccharide layer that degrades not more than 20% weight within two years or an external polysaccharide layer that degrades at least 50% by weight with in 100 days as claimed by the applicant.

Collombel teaches the usage of chitosan in a biomaterial application where the speed of enzymatic degradation of chitosan is a function both of its molecular weight and its degree of acetylation (Column 5, lines 64-66).

Pastorello teaches that the chemical structure of the hyaluronic acid derivative used and according to the degree of esterification have the advantage of having tensile strength and degradation times that can be adjusted according to the requirement of the area to be reconstructed (Column 3, lines 55-61).

Whereas, Elliot teaches a biocompatible coating for implantable prosthesis which can be composed of hyaluronic acid and chitosan. Pastorello and Collombel teach that both hyaluronic acid and chitosan can be selected with the appropriate structural features (esterification in hyaluronic acid and acetylation in chitosan) to control the degree of degradation.

It would have been obvious to some of ordinary skill in the art at the time of the invention to combine the biocompatible hyaluronic acid and chitosan implantable prosthesis coating taught by Elliot with the suitable structural features (esterification in

hyaluronic acid and acetylation in chitosan) taught by Pastorello and Collombel to give the desired degradation properties in the respective layers.

The process would involve ensuring that through routine experimentation the materials in the external and internal regions have a sufficient molecular weight and a suitable level of acetylation with respect to the chitosan material based on the teachings of Collombel and the appropriate degree of esterification with respect to the hyaluronic acid material based on the teachings of Pastorello to achieve the desired degradation rate in the internal and external regions. Through such routine experimentation, a person of ordinary skill in the art at the time of the invention could achieve a degradation that is slowed from the outside direction of the main body of the implant, an internal polysaccharide layer that degrades not more than 20% weight within two years or an external polysaccharide layer that degrades at least 50% by weight within 100 days as claimed by the applicant.

11. Regarding Claim 15, 17-19, Elliot, Pastorello and Collombel do not teach the thickness of the polysaccharide layer as be 3 to 50 microns for the internal layer, 10 to 250 microns for the external layer, 10 to 400 microns or 50-120 microns in thickness.

With a reasonable expectation of successful results, it would have been obvious to one having ordinary skill in the art at the time of the invention to adjust the internal and the external thicknesses for the polysaccharide layers with respect to the desired degradation rate through routine experimentation of implant coating levels to

determine the appropriate amount for proper surface coverage which would include the ranges claimed by the applicant. In the course of determining the optimal thickness the ranges covered by the applicant would be in scope, absence unexpected results.

12. **Regarding Claim 20**, Elliot teaches the use of hyaluronic acid, chitosan, and/or other polysaccharide as coating for implantable prostheses. Elliot, Pastorello and Collombel do not teach that hyaluronic acid or its derivatives and chitosan are components of a polysaccharide layer as individual substances, copolymers, block polymers made of hyaluronic acid or its derivatives and chitosan or in the form of mixtures.

The examiner takes the position that Elliot, Pastorello and Collombel all disclose that hyaluronic acid and chitosan can be used as biodegradable coating materials for implants. The simple combining of two polysaccharide materials for which the cited references clearly reads upon is not considered as patentable subject matter. In addition, the simply transesterification of hyaluronic acid and chitosan is achieved by a well known condensation polymerization and the use copolymers which result as implant coatings is not considered as patentable subject matter.

13. **Regarding Claims 24 and 25**, Elliot teaches an implantable prosthesis which may be used as a graft to replace a portion of a bodily passageway (e.g., vascular graft), or may be used within a bodily such as an endovascular stent-graft (paragraph

20). Elliot teaches that the skirt (outer covering the prosthesis) can be coated with materials that are susceptible to cell ingrowth (tissue simulating) (paragraph 25). These materials include: collagen, fibrin, hyaluronic acid, chitosan, and/or other polysaccharide (paragraph 25).

14. Claim 21 is rejected under 35 U.S.C. 103(a) as being unpatentable over Elliot (2003/0236567)/Collombel (5,166,187) in view of Pastorello (6,642, 213) and Swan (5,563,056).

15. **Regarding Claim 21**, Elliot, Collombel and Pastorello do not teach the polysaccharide is immobilized covalently or through physisorption on the surface of the implant as claimed by the applicant.

Swan teaches a chemical specie can be immobilized in a three dimensional, crosslinked matrix by bringing together in covalent bonding proximity a desired chemical specie and a polymeric coupling compound such as a photoderivatized polymer having at least two latent photochemical reactive groups per molecule, each latent reactive group being capable when activated of covalently bonding to another coupling compound molecule or to the chemical specie (abstract). Swan also teaches such materials which are readily coupled (immobilized) to a surface include oligomers, homopolymers and copolymers resulting from addition or condensation polymerization, and natural polymers including nucleic acids, oligosaccharides, linear polysaccharides such as amylose, dextran, chitosan, heparin and hyaluronic acid,

and branched polysaccharides such as amylopectin, glycogen and hemi-celluloses (Column 3, lines 54-63). Swan also teaches that the immobilization of chemical species (on the surfaces of prostheses that are to be implanted within the body) with growth factors or similar chemical species may contribute to the rapid proliferation of tissue (biocompatibility/ tissue growth) on the prosthesis (Column 1, lines 21-25).

Whereas both chitosan and hyaluronic acid homopolymers and copolymers can be immobilized on a surface covalently it would have been obvious to someone of ordinary skill in the art at the time of the invention to combine the metallic implant coatings taught by Elliot with the immobilization technique taught by Swan to improve biocompatibility/ tissue growth, absent of unexpected results.

16. Claims 1,3-7, 9-20 are rejected under 35 U.S.C. 103(a) as being unpatentable over Wironen (6,685,626) and Collombel (5,166,187) in view of Pastorello (6,642, 213).

17. Regarding Claim 1, Wironen teaches a biocompatible (Column 5, lines 43-45) coating (called by the term "a carrier", Column 4, lines 14-20) system for metallic implants (Column 4, lines 30-35). The carrier coating selected from or may be a combination of materials selected from the following non-exclusive list: collagen; gelatin; carboxymethyl cellulose; hyaluronic acid; polyvinyl alcohol; thrombin; fibrin; albumin; and mucoadhesive polysaccharides such as chitosan, polyalcohols, polyamines, polyvinyls, polyamides and polyesters (Column 5, lines 9-17).). *The*

carrier coating *is* selected from or may be a combination of materials which include hyaluronic acid and chitosan (Column 5, lines 9-17).

The examiner takes the position that Wironen teaches a combination of materials can be used in a single polysaccharide coating layer which reads on the instant "a polysaccharide layer made of chitosan and hyaluronic acid/ hyaluronic acid derivative".

Wironen does not teach a composition such the *in vivo* degradation of the polysaccharide layer is slowed from the outside in the direction of the main body of the implant.

Collombel teaches chitosan is used coat prostheses (column 14, lines 2-5) and the speed of enzymatic degradation of chitosan is a function both of its molecular weight and its degree of acetylation (Column 5, lines 64-66).

Pastorello teaches that the chemical structure of the hyaluronic acid derivative used and the degree of esterification allow the degradation times to be adjusted according to the requirement of the area to be reconstructed (Column 3, lines 55-61).

Whereas, Wironen teaches an implantable prosthesis which can be composed of hyaluronic acid and chitosan. Pastorello and Collombel teach that both hyaluronic acid and chitosan can be selected with the appropriate structural features (esterification in hyaluronic acid and acetylation in chitosan) to control the degree of degradation in a given region.

In addition, the simple esterification of hyaluronic acid and acetylation of chitosan is achieved by a well known condensation reaction procedures. Moreover, the

blocking of reactive organic groups such as the carboxylic acid group or the hydroxyl group is a well known method to decrease the reactivity of an organic material to a given medium. To control the degradation rate a person skilled in the art would conduct routine experiments to ensure that a suitable percentage of reactive organic groups were blocked to control the degradation rate.

The examiner takes the position that Collombel and Pastorello teaches the very structural features (acetylated substituents) and molecular weight requirements necessary for a person of ordinary skill in the art at the time of the invention to formulate a prosthetic coating with a controlled degradation rate in a given region.

The process would involve ensuring through routine experimentation that the chitosan on the external portion of the coating structure has a sufficient molecular weight and a suitable level of acetylation to slow the polysaccharide degradation by a desired amount for the intended application. Likewise, ensuring through routine experimentation that the hyaluronic acid on the external portion of the coating structure have a suitable level of esterification to slow the polysaccharide degradation by a desired amount for the intended application.

With a reasonable expectation of success, a person of ordinary skill in the art with the teachings of Wironen, Collombel and Pastorello would modify the chitosan and the hyaluronic acid of Wironen with the acetylated chitosan of Collombel and the esterified hyaluronic acid of Pastorello in order control the rate of degradation.

The motivation for combining the references would have been to utilize known techniques to control the degradation rates of chitosan and hyaluronic acid on coated

implants to improve compatibility with surrounding tissue and decrease the likelihood of infection.

18. **Regarding Claims 3**, Wironen teaches the usage of a mucoadhesive polysaccharide layer which contains chitosan (Column 5, lines 14 and 15).

19. **Regarding Claim 4**, Wironen teaches the usage of a mucoadhesive polysaccharide layer which contains chitosan (Column 5, lines 14 and 15). The adhesion-promoting material is applied to the implant material in the form of a sheet (layer) to promote adherence to the tissue surfaces (column 5, lines 24-30). The applicant claims a thickness of 1 to 50 microns. Wironen does not teach the thickness of the chitosan layer.

With a reasonable expectation of successful results, it would have been obvious to one having ordinary skill in the art at the time of the invention to adjust the thickness for the chitosan layer to ensure that a sufficient amount of the adhesive layer was present to hold the implant in the desired position, without slippage, to better ensure long-lasting results (column 5, lines 58-62).

20. **Regarding 5**, Wironen teaches a biocompatible (Column 5, lines 43-45) coating (called by the term "a carrier", Column 4, lines 14-20) system for metallic implants (Column 4, lines 30-35). The carrier (coating) material is selected from or may be a combination of materials selected from the following non-exclusive list: collagen;

gelatin; carboxymethyl cellulose; hyaluronic acid; polyvinyl alcohol; thrombin; fibrin; albumin; and mucoadhesive polysaccharides such as chitosan, polyalcohols, polyamines, polyvinyls, polyamides and polyesters (Column 5, lines 9-17). The applicant teaches a total weight of polysaccharide of not more than 50% weight.

Wironen also teaches that a coating where gelatin is used in the amount of 1-70% weight and preferably 25 to 40% weight (column 6, lines 10-12). The examiner takes the position that both gelatin and chitosan are listed by Wironen as materials that can be used for coating materials and chitosan could be used in place of gelatin.

The applicant teaches a chitosan range of less than 50%. The weight range taught by Wironen covers the entire range taught by the applicant and the preferred range is within the scope of that taught by the applicant.

Wironen and the claim differ in that Wironen does not teach the exact same proportions as recited in the instant claim.

However, one of ordinary skill in the art at the time the invention was made would have considered the invention to have been obvious because the compositional proportions taught by Wironen overlap the instantly claimed proportions and therefore are considered to establish a prima facie case of obviousness. It would have been obvious to one of ordinary skill in the art to select any portion of the disclosed ranges including the instantly claimed ranges from the ranges disclosed in the prior art reference, particularly in view of the fact that;

"The normal desire of scientists or artisans to improve upon what is already generally known provides the

motivation to determine where in a disclosed set of percentage ranges is the optimum combination of percentages", In re Peterson 65 USPQ2d 1379 (CAFC 2003).

Also, In re Geisler 43 USPQ2d 1365 (Fed. Cir. 1997); In re Woodruff, 16 USPQ2d 1934 (CCPA 1976); In re Malagari, 182 USPQ 549, 553 (CCPA 1974) and MPEP 2144.05.

21. Regarding Claims 6 and 7, Wironen teaches a biocompatible (Column 5, lines 43-45) coating (called by the term "a carrier", Column 4, lines 14-20) system for metallic implants (Column 4, lines 30-35). The carrier (coating) material *is* selected from or may be a combination of materials selected from the following non-exclusive list: collagen; gelatin; carboxymethyl cellulose; hyaluronic acid; polyvinyl alcohol; thrombin; fibrin; albumin; and mucoadhesive polysaccharides such as chitosan, polyalcohols, polyamines, polyvinyls, polyamides and polyesters (Column 5, lines 9-17). Wironen does not teach an average molecular weight of the hyaluronic acid or hyaluronic acid derivative between 300,000 and 500,000 Dalton or between 380,000 and 420,000 Dalton at claimed by the applicant.

With the reasonable expectation of success, a person of ordinary skills in the art at the time of the invention through routine experimentation would adjust the molecular weight of hyaluronic acid or its derivatives based on the amount of durability required for that component. Hyaluronic acid or its derivatives with higher

molecular weights would be expected to be more durable than hyaluronic species with lower molecular weights. The determination of the appropriate average molecular weight would overlap with the ranges taught by the applicant in the course of optimization.

22. Regarding Claims 9 and 11, Wironen does not teach that the internal area of the polysaccharide layer is not degradable, at least completely within two years or the external polysaccharide layer is degradable with in 100 days as claimed by the applicant.

Collombel teaches the usage of chitosan in a biomaterial application where the speed of enzymatic degradation of chitosan is a function both of its molecular weight and its degree of acetylation (Column 5, lines 64-66).

Pastorello teaches that the chemical structure of the hyaluronic acid derivative used and according to the degree of esterification have the advantage of having tensile strength and degradation times that can be adjusted according to the requirement of the area to be reconstructed (Column 3, lines 55-61).

Whereas, Wironen teaches a biocompatible coating for metallic implants which can be composed of hyaluronic acid and chitosan. Collombel and Pastorello teach that both hyaluronic acid and chitosan can be selected with the appropriate structural features (esterification in hyaluronic acid and acetylation in chitosan) to control the degree of degradation.

It would have been obvious to some of ordinary skill in the art at the time of the invention to combine the biocompatible hyaluronic acid and chitosan coating metallic implant coating taught by Wironen with the suitable structural features (esterification in hyaluronic acid and acetylation in chitosan) taught by Pastorello and Collombel to give the desired degradation properties in the respective layers to improve tissue compatibility and decrease the likelihood of infection.

23. Regarding Claims 10 and 12, Wironen, Pastorello, and Collombel do not teach an internal of polysaccharide layer thickness of 3 to 50 microns or an external thickness of 10 to 250 microns as claimed by the applicant.

With a reasonable expectation of successful results, it would have been obvious to one having ordinary skill in the art at the time of the invention to adjust the internal and the external thicknesses for the polysaccharide layers through routine experimentation of implant coating levels to determine the appropriate amount which would include the ranges claimed by the applicant.

24. Regarding Claims 13, 14, 16, Wironen teaches a biocompatible (Column 5, lines 43-45) coating (called by the term "a carrier", Column 4, lines 14-20) system for metallic implants (Column 4, lines 30-35). *The carrier (coating selected from or may be a combination of materials selected from the following non-exclusive list: collagen; gelatin; carboxymethyl cellulose; hyaluronic acid; polyvinyl alcohol; thrombin; fibrin; albumin; and mucoadhesive polysaccharides such as chitosan, polyalcohols,*

polyamines, polyvinyls, polyamides and polyesters (Column 5, lines 9-17). Wironen implies that one may select a material from the list shown above or a combination of material which the examiner interrupts to include if desire layers using chitosan or hyaluronic acid or combination thereof.

Wironen, Pastorello, and Collombel do not teach a composition such the vivo degradation of the polysaccharide layer is slowed from the outside in the direction of the main body of the implant, an internal polysaccharide layer that degrades not more than 20% weight within two years or an external polysaccharide layer that degrades at least 50% by weight with in 100 days as claimed by the applicant.

Collombel teaches the usage of chitosan in a biomaterial application where the speed of enzymatic degradation of chitosan is a function both of its molecular weight and its degree of acetylation (Column 5, lines 64-66).

Pastorello teaches that the chemical structure of the hyaluronic acid derivative used and the degree of esterification allow the degradation to be adjusted according to the requirement of the area to be reconstructed (Column 3, lines 55-61).

Whereas, Wironen teaches a biocompatible coating for implantable prosthesis which can be composed of hyaluronic acid and chitosan. Pastorello and Collombel teach that both hyaluronic acid and chitosan can be selected with the appropriate structural features (esterification in hyaluronic acid and acetylation in chitosan) to control the degree of degradation.

It would have been obvious to some of ordinary skill in the art at the time of the invention to combine the biocompatible hyaluronic acid and chitosan implantable

prosthesis coating taught by Wironen with the suitable structural features (esterification in hyaluronic acid and acetylation in chitosan) taught by Pastorello and Collombel to give the desired degradation properties in the respective layers.

The process would involve ensuring that through routine experimentation the materials in the external and internal regions have a sufficient molecular weight and a suitable level of acetylation with respect to the chitosan material based on the teachings of Collombel and the appropriate degree of esterification with respect to the hyaluronic acid material based on the teachings of Pastorello to achieve the desired degradation rate in the internal and external regions. Through such routine experimentation, a person of ordinary skill in the art at the time of the invention could achieve a degradation that is slowed from the outside direction of the main body of the implant, an internal polysaccharide layer that degrades not more than 20% weight within two years or an external polysaccharide layer that degrades at least 50% by weight within 100 days as claimed by the applicant.

25. **Regarding Claim 15, 17-19**, Wironen, Pastorello and Collombel do not teach the thickness of the polysaccharide layer as be 3 to 50 microns for the internal layer, 10 to 250 microns for the external layer, 10 to 400 microns or 50-120 microns in thickness.

With a reasonable expectation of successful results, it would have been obvious to one having ordinary skill in the art at the time of the invention to adjust the internal and the external thicknesses for the polysaccharide layers with respect to the desired

degradation rate through routine experimentation of implant coating levels to determine the appropriate amount which would include the ranges claimed by the applicant. In the course of determining the optimal thickness the ranges covered by the applicant would be in scope, absence unexpected results.

26. **Regarding Claim 20**, *Wironen*, Pastorello and Collombel teach the invention of claim 8. *Wironen teaches a biocompatible* (Column 5, lines 43-45) coating (called by the term "a carrier", Column 4, lines 14-20) system for metallic implants (Column 4, lines 30-35). *The carrier coating is selected from or may be a combination of materials which include hyaluronic acid and chitosan* (Column 5, lines 9-17).

27. **Claim 21 is rejected under 35 U.S.C. 103(a) as being unpatentable over Wironen (6,685,626)/Collombel (5,166,187) in view of Pastorello (6,642, 213) and Swan (5,563,056).**

28. **Regarding Claim 21**, *Wironen*, Collombel and Pastorello do not teach the polysaccharide layer is immobilized covalently or through physisorption on the surface of the implant.

Swan teaches a chemical specie can be immobilized in a three dimensional, crosslinked matrix by bringing together in covalent bonding proximity a desired chemical specie and a polymeric coupling compound such as a photoderivatized polymer having at least two latent photochemical reactive groups per molecule, each

latent reactive group being capable when activated of covalently bonding to another coupling compound molecule or to the chemical specie (abstract).

Swan also teaches such materials which are readily coupled (immobilized) to a surface include oligomers, homopolymers and copolymers resulting from addition or condensation polymerization, and natural polymers including nucleic acids, oligosaccharides, linear polysaccharides such as amylose, dextran, chitosan, heparin and hyaluronic acid, and branched polysaccharides such as amylopectin, glycogen and hemi-celluloses (Column 3, lines 54-63). Swan also teaches that the immobilization of chemical species (on the surfaces of prostheses that are to be implanted within the body) with growth factors or similar chemical species may contribute to the rapid proliferation of tissue (biocompatibility/ tissue growth) on the prosthesis (Column 1, lines 21-25).

Whereas both chitosan and hyaluronic acid homopolymers and copolymers can be immobilized on a surface covalently it would have been obvious to someone of ordinary skill in the art at the time of the invention to combine to biocompatible metallic implant coatings taught by Wironen with the immobilization technique taught by Swan to improve biocompatibility/ tissue growth, absent of unexpected results.

Response to Arguments

The applicant's arguments have been considered but as consider moot based on the new round of rejections. The use of chitosan and hyaluronic acid as implant coatings

is well known and the combining of such materials is also mentioned in the art by Wironen. The biodegradable nature of a material is related to the ultimate affinity between the implant coating and the surrounding tissue. Controlling the rate of degradation of chitosan and hyaluronic acid copolymers or mixture would be desirable because the rate of degradation will affect the rate at which surrounding tissue establishes vascular connectivity to the biopolymers and decrease the likelihood of infection. While Collombel does not mention applying chitosan as a coating, the use of chitosan as an implant coating is well known in the art as taught by Elliot and Wironen. Using the methods taught by Collombel to control degradation of a biomaterial by functionalization was well known in the art at the time of the invention. A similar argument can be made for the method to control degradability of biomaterials disclosed by Pastorello. Although the Pastorello uses hyaluronic acid as composite material for implants as opposed to a coating for the actual implant, the usable knowledge of how control the degradation of this material was common in the art at the time of the invention. The techniques of Collombel and Pastorello as applied to chitosan and hyaluronic acid (two material with known implant coating utility) to control degradation rate were readily available at the time of the invention and a skilled artisan seek up such facile techniques which would improve the compatibility of the coating implant with the surrounding tissue. The pendant groups present on chitosan (hydroxyl groups) and hyaluronic acid (carboxylic acid groups) would be very amenable to the immobilization techniques of Swan.

Conclusion

The prior art made of record and not relied upon is considered pertinent to applicant's disclosure. Machan et. al. US 20020065546 teach biodegradable copolymers of chitosan and hyaluronic acid in metallic implants.

Applicant's amendment necessitated the new ground(s) of rejection presented in this Office action. Accordingly, **THIS ACTION IS MADE FINAL**. See MPEP § 706.07(a). Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire **THREE MONTHS** from the mailing date of this action. In the event a first reply is filed within **TWO MONTHS** of the mailing date of this final action and the advisory action is not mailed until after the end of the **THREE-MONTH** shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than **SIX MONTHS** from the date of this final action.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to GREGORY CLARK whose telephone number is (571)270-7087. The examiner can normally be reached on M-Th 7:00 AM to 5 PM Alternating Fri 7:30 AM to 4 PM and Off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Larry Tarazano can be reached on (571) 272-1515. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see <http://pair-direct.uspto.gov>. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.
